

2.2.1 - 2.2.4 Project Documentation

In this project, I built a game that searches a randomly generated phrase, chosen from a txt file, for a specific character, generates point values based on whether the character was present, and switches between players otherwise. To do this, I wrote accessors and mutators for the Player class, implementing them in the PhraseSolver file. In the PhraseSolver file, my algorithm created 2 Players and a Board object. I then wrote the play() method, which created a Scanner object to track user input and used if/else conditionals to check whether a guessed letter was within a phrase or not, or whether the guessed phrase matched the one randomly generated from the phrases.txt file. I used modulus operators to track whose player's turn it was, and used a while loop to continue the game until the phrase was guessed correctly.

In the Player class, I defined a new Scanner object that would take the inputted name, setting the name to "AP Grader" if all characters were not letters, checked using a for loop. I introduced points as an attribute for Player, changing its value and printing the player's points depending on whether they guessed well.

Below is the GitHub repository with all relevant code, including the Board, Player, PhraseSolver, and Runner java and class files, a screen recording of the project running, and the txt file containing the list of usable phrases.
